Award Year: 2015

Project Title: "Cure4PMP – genomic biomarkers and actionable targets"

Project Status: Active

Update 3 (07-2017)

Our hypothesis is that by obtaining in-depth knowledge of the molecular composition of PMP, treatment of this debilitating disease will be improved. The long-term goal of this research is therefore to provide a cure for more patients with PMP, and for patients that cannot be cured, the goal is to search for drug targets and drugs that can inhibit tumour growth to prevent disease progression and alleviate symptoms.

In the Cure4PMP project we will analyse a substantial number of PMP samples to identify clinically useful molecular biomarkers therapeutic targets. A challenge is that many samples contain a lot of mucin, but very few tumour cells, and in the first part of the project we have tested methods for analysis of such samples. Using targeted deep sequencing we have been able to identify mutations in samples with very low tumour cell count, completing this task.
